Abstract

Getting started with data science is a daunting task, particularly when it requires a large amount of coding before you can even start looking at data. Graphical user interfaces (GUIs) have often been used as a way of proving novice users the ability to interact with complex systems without the need for coding. However, many of these themselves have steep learning curves to understand how to make the software do what's needed, and do not provide a pathway to more standard and flexible methods, such as coding. **iNZight** is a GUI based tool written in R that provides students of statistics and data science the opportunity to interact with data and explore without first learning to code. The tool is designed to be easy to use, with logical interactions and clever defaults. However, it also provides some more complex features to manipulate and analyse data, and further provides a code history of the actions performed, creating a pathway between GUI and learning to code for those interested in progressing into the more open and exciting world of data science.

Keywords: GUI, statistical software, statistical education, R.

1. Introduction

The R programming environment (R Core Team 2020) is an open source, easy to learn statistical programming environment used throughout statistics and data science and backed by a repository of thousands of packages targeting even the most unique of problems. Amongst these packages are several graphical user interfaces (GUIs) providing point-and-click methods for creating graphs, performing hypothesis tests, and a range of other statistical methods,

with two prominent examples being R Commander (Fox 2005) and **Deducer** (Fellows 2012). R Commander includes a full interface which displays, writes, and runs code, while **Deducer** extends the R console with additional menus to open window interfaces to a range of methods. These tools allow users to perform known procedures using point-and-click interfaces without needing to remember function and argument names. This does, however, require that users know what thay want to achieve, which excludes many beginner users who are yet to learn these technical terms.

An alternative approach is to work variable-first: users select the variables they are interested in, and then choose from an automatically generated list of methods to perform. **iNZight** uses this approach, presenting users with an exploration-focussed interface emphasising graphics, which are at the core of exploratative data analysis. After visually exploring their data, users can produce summary statistics and inference information with the click of a button—**iNZight** shows information relevant to the chosen variables. For hypothesis testing, users choose from a list of tests applicable to the variables displayed in the graph without having the recall specific names. This makes **iNZight** ideal for users who are completely new to statistics and data science, and those who seldom perform specific tasks and might otherwise struggle to remember the terminology required if using alternative software.

Like other GUIs, there is a code component. R Commander provides a place for users to enter R code, while **Deducer** sits on top of the R console using the environment as-is. With **iNZight**, however, code is evaluated "behind the scenes", and is not directly editable by users. Every action the user makes calls one or more R functions, the code for which is added to the *code history* for users to review, save, and share. This allows users to generate an R script unique to their data and later edit and run the code manually in R, providing a stepping stone between GUI and code.

Due in part to its ease of use, **iNZight** has been adopted throughout New Zealand's statistical education program. Final year high school students are introduced to basic statistical concepts using **iNZight**, including a foray into time series analysis, while universities across the country are using **iNZight** in both introductory and advanced statistics courses. This paper provides an overview of **iNZight**'s main features, technical details of its development, an introduction to the *add-on* system, and a description of the install process.

2. A tour of iNZight's features

The primary audience for **iNZight** is students of statistics and data science, but secondary groups include small research groups and organisations with small budgets who may perform commonplace statistical analyses infrequently. The interface's simplicity, shown in Figure 1, makes it easy to learn initially and re-learn after a period of non-use unlike more complex alternatives. To achieve this, we made the interface as intuitive as possible, with self-explanatory controls using basic simple drag-and-drop or drop-down selection mechanisms. **iNZight** also uses a *variable-first* approach, allowing users to choose the variables they are interested in and let the software display the relevant actions. The easiest way to explore **iNZight**'s features is by demonstration.

2.1. Loading data

Data comes in a wide range of formats, some of which are typically software-dependent (such

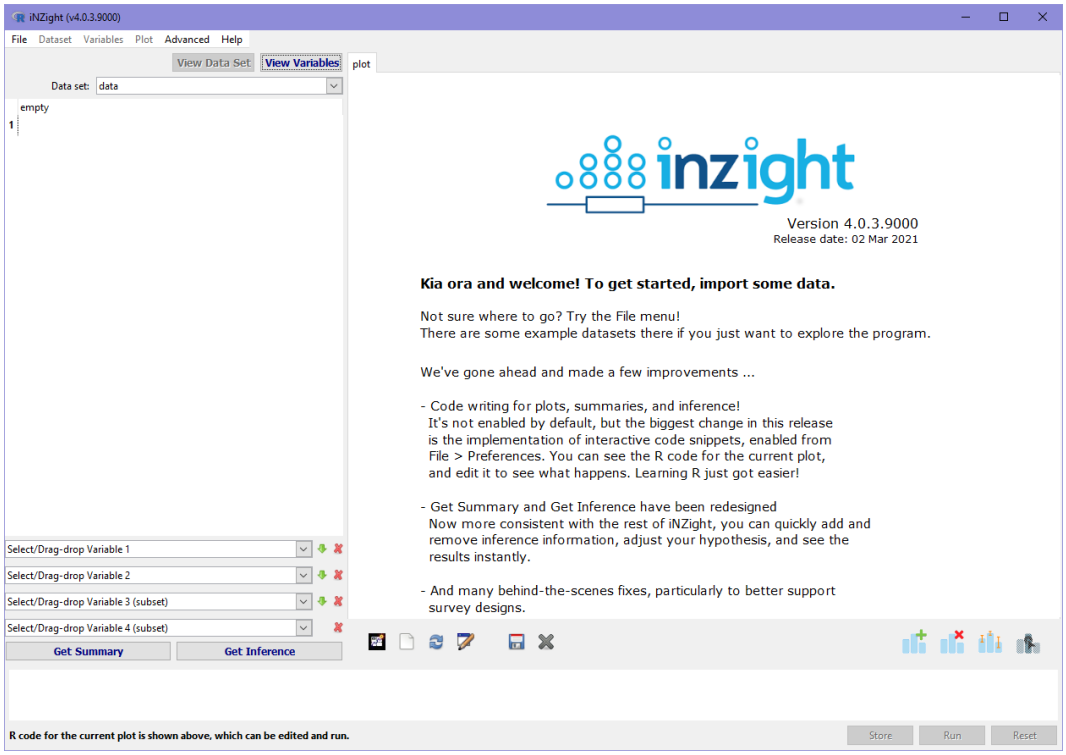

Figure 1: The **iNZight** GUI landing page presents users with a few controls. The screen will update once data has been loaded.

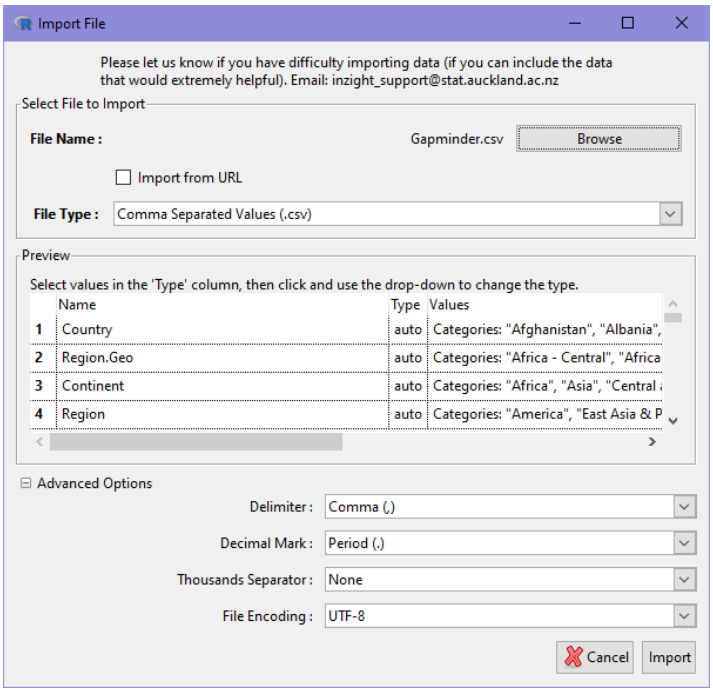

Figure 2: Load Data window, showing the chosen file, the File Type (guessed from the extension), and a preview of the data.

as Excel files, Microsoft Corporation 2018). Due in part to being open source, there are 1000's of R packages on the Comprehensive R Archive Network (CRAN), amongst which are some dedicated to reading specific file formats. However, users must still know the correct package and function for their files, and argument names and order. **iNZight** provides a simple Load Data window from which users can select a file to import, at which point the software detects the file type from the file extension and attempts to read the file. If successful, a preview is displayed for the user to check before proceeding to import the file. Figure 2 shows the Load Data window, which has detected a comma separated values (CSV) file and used the appropriate function in the background. Currently, **iNZight** supports files in CSV, tab-delimited, Excel, SAS, Stata, SPSS, R-data, and JSON formats.

In addition to the preview, **iNZight** also has an Advanced Options section for some specific formats. Currently only delimited files have advanced options, where users can override the default delimiter, for example in European countries where the semi-colon (;) is used (the comma is reserved as the decimal separator), as well as different encoding formats. The preview is updated when these options are changed, so users do not have to know specifically what they need, and can use trial-and-error to get the preview looking right before importing the data into **iNZight**.

2.2. Creating graphs

Within **iNZight**, graphics are at the core of the user experience: the first prototype included a drag-and-drop of variables to create a plot, and that is how things have remained. Behind the scenes, **iNZight** detects the variable types (numeric, categorical, or a date-time) and draws an appropriate graph. For example, a single numeric variable produces a dot plot, while a categorical variable produces a bar chart. The user does not need to know what type of graph they want to create from a chosen variable, allowing them to freely explore the dataset by drag-and-drop of variables onto the Variable boxes (or using the drop down menus).

The first variable box is referred to as the *Primary Variable of Interest*. That is, this is the variable we want to know about, and how it is influenced by other variables. For example, if *height* is chosen as Variable 1, and we want to know how height changes with ethnicity or age; in the latter case, the result will be a scatter plot *with height on the y-axis*. In addition to the first two variable slots, **iNZight** includes two subset variables to quickly and easily facet the plot and explore more complex relationships and interactions.

Finally, there is an entire panel dedicated to plot modifications: Add to Plot. This is accessed either from the Plot menu, or from the button in the Plot Toolbar (boxed in red in Figure 3). From here, users can choose from a selection of alternative plot types (limited by the types of variables), as well as choose a colour variable, sizing variable, plot symbols, trend lines, changing axis labels and limits, and much more. The options are presented in an interactive format such that the graph updates whenever the user changes input values, allowing them to explore "what happens if ...", and "what does this do?". The goal is to let beginners explore a dataset without being limited by a lack of knowlede and coding skill—that comes later. Figure 3 shows a graph produced by **iNZight** exploring the relationship between infant mortality and GDP, region, population, and year.

2.3. Summaries and inference

To supplement the visual graphics, **iNZight** also provides two textual output modes: *sum-*

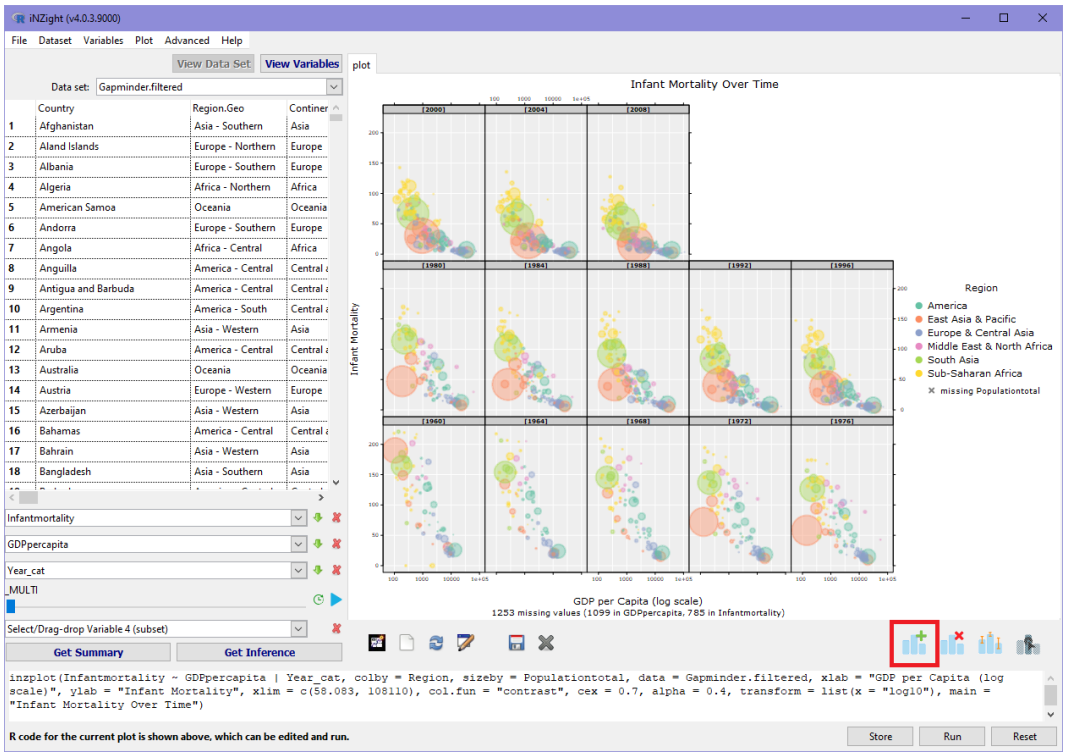

Figure 3: Demonstration of plot modifcations available from **iNZight**'s ADD TO PLOT menu. The ADD TO PLOT button, highlighted in red, opens a panel giving user control over colours, size, shape, labels, and much more.

maries and *inference*, accessed from the GET SUMMARY and GET INFERENCE buttons, respectively, at the bottom-left of the interface. Summary information includes basic information about the chosen variables, including mean, standard deviation, quantiles, and so on, acting as a quick reference for values that are likely estimable from the graph itself.

The inference information provides estimated, confidence intervals, and any applicable p-values, for quantities such as means and proportions, and a simple interface for performing hypothesis tests. **iNZight** displays a selection of tests available for the chosen variable(s), as shown in Figure 4. The full list of tests available are given in Table 1. The inference information can either be calculated using Normal theory or bootstrap methods (using the **boot** package, Canty and Ripley 2020).

2.4. Data wrangling

Usually the first step researchers want to take when they first begin exploring a dataset is to create a set of exploratory graphs. However, it is often not possible to get the correct graphs from the raw data alone. Applying transformations and other modifications to the data can allow researchers to explore the data correctly or from a different perspective. **iNZight** contains two *data manipulation* menus: DATA and VARIABLES. The former acts on the data set as a whole, while the later creates modified versions of existing columns (variables).

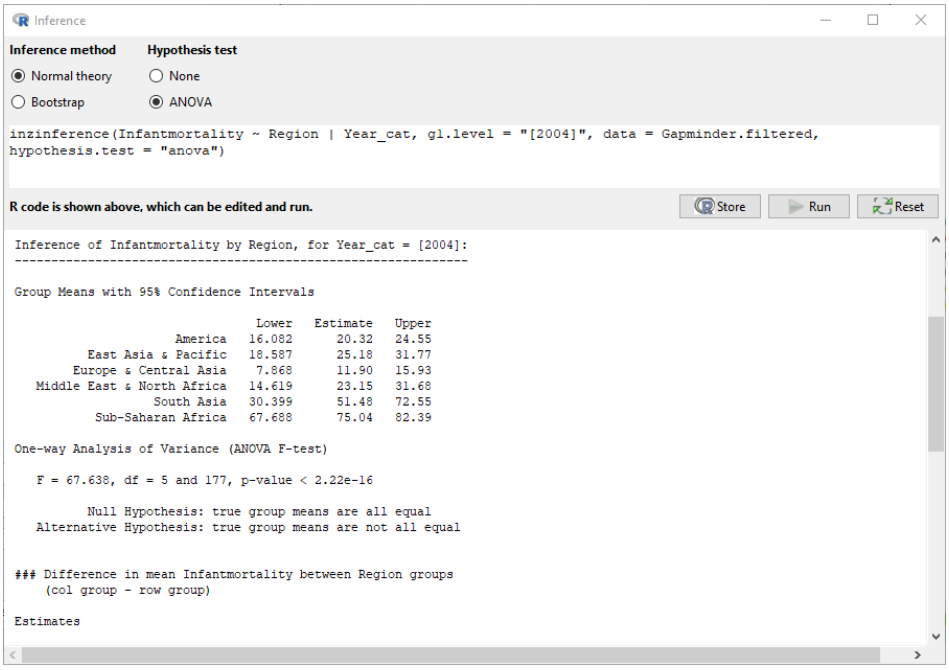

Figure 4: The INFERENCE window provides a selection of hypothesis tests for the chosen variables. In this case, these are `Infantmortality` (a numeric variable) and `Region` (categorical with six levels), so **iNZight** provides an ANOVA test.

Table 1: iNZight hypothesis test options.

Variable 1		Variable 2			
		NULL	numeric	2 level cat	2+ level cat
numeric		t-test[1]	–	t-test[3]	ANOVA
categorical	2 levels	single proportion	t-test[3]	χ^2-test[4,5]	χ^2-test[4,5]
	2+ levels	χ^2-test[2]	ANOVA	χ^2-test[4]	χ^2-test[4]

[1] One-sample
[2] Equal proportions
[3] Two-sample
[4] Equal distributions
[5] Additionally includes epidemiological output such as odds and risk ratios.

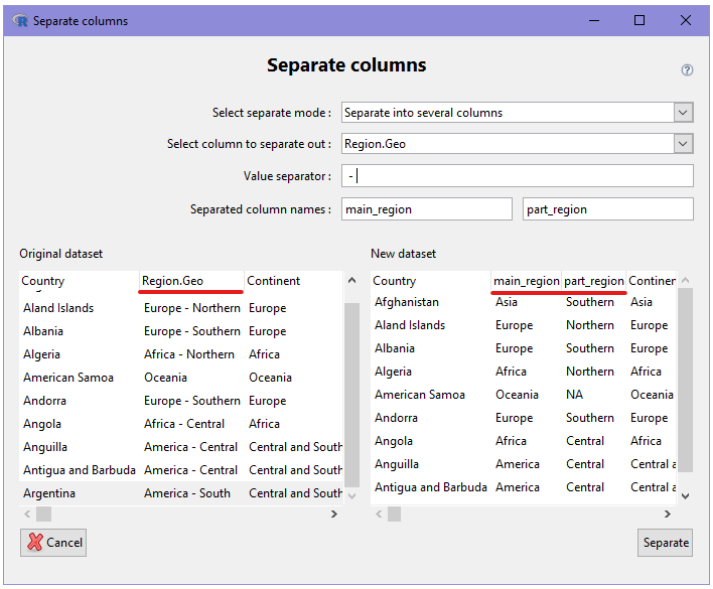

Figure 5: Here, the user is separating a column to create two new variable, with the preview displayed in the bottom-right. The relevent column names are underlined in red. The preview uses the first few rows of the data, and updates in real-time, reacting to changes the user makes, allowing them to experiment easily.

In their book *R for Data Science*,[1] Wickham and Grolemund (2017) describe many data manipulation methods including filtering, aggregation, and reshaping. They provide the **tidyverse** (Wickham *et al.* 2019) code for these actions, which **iNZight** uses behind-the-scenes to implement the behaviours. However, **iNZight** provides a GUI interface to these (often complex) methods, allowing users to quickly and easily filter by value, convert from *wide* to *long* form, or merge two related datasets together. In most cases, the interface allows users to fill out the fields which change according to previous selections, and at the bottom is a preview of what the data will look like, as demonstrated in Figure 5.

Supplementary to the dataset operations, the VARIABLE menu provides a selection of variable transformation and modification actions. For example, numeric variables can be converted to categorical (a common example is `Year`), or categoric variable levels can be renamed, reordered, and combined. Users also have the option of creating custom variables using R code, as well as renaming and deleting entire variables. In most cases, **iNZight** creates a *new* variable, for example converting `Year` to categorical yields the variable `Year.cat`, which makes the experience more exploration-friendly.

2.5. Special data types

Many data sets that beginners are exposed to are in 'tidy' format (Wickham and Grolemund 2017),[2] such that rows are individual records and columns observations. However, there are some unique data types that are common for beginners to encounter, or form a core component of statistical education. These data sets require unique graphics or other special handling to

[1] check
[2] check citation

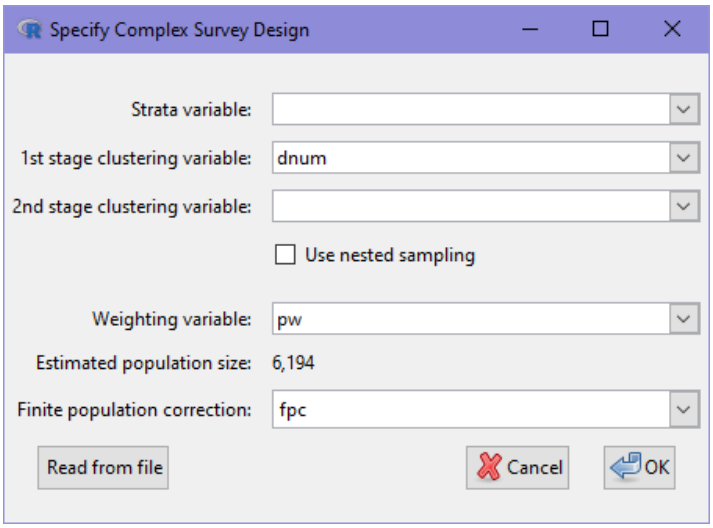

Figure 6: Users can specify survey design information manually by filling in the fields. These will then be used throughout the session.

explore correctly, a task which **iNZight** has been extended to perform. Some such examples are described here.

Complex survey designs

One of the most important data types for official statistics and research groups are complex surveys, and require information about the survey's structure to provide valid graphs, summaries, and inferences. **iNZight** handles survey designs behind the scenes, and requires the user to specify the structure manually (Figure 6) or by importing a special *survey design* file which can be distributed with the data. Once specified, the user can forget about the survey design and use **iNZight** as normal: survey weights are incorporated correctly into graphs, summaries, and data manipulation functions using the **survey** (Lumley 2004) and **srvyr** (Freedman Ellis and Schneider 2020) packages behind the scenes; the latter is a wrapper package providing **dplyr**-like syntax for surveys.

iNZight handles several types of designs: stratified, one- and two-stage cluster surveys, and replicate weight designs. In the former, information about the strata and clusters is contained within the dataset. However, in the interest of confidentiality,[3] some survey datasets use *replicate weights*, allowing variance estimation without exposing strata and cluster information (Lumley 2010). In addition to these, **iNZight** also provides functionality to calibrate surveys with data from other sources to reduce the estimation variances (**?**). Once again, this is performed once by the user and the used continually throughout the rest of **iNZight**.

The types of graphs available differ for survey data. For a single numeric variable, a *histogram* is displayed by default instead of a dotplot. For two numeric variables, a *bubble plot* is used, which is effectively a scatter plot with points sized by the respective weights of observations. Alternatively, this can be displayed as a *hex* plot also. Bar plots remain the same, while summaries accessed from the Get Summary button display the same information, but are

[3] check

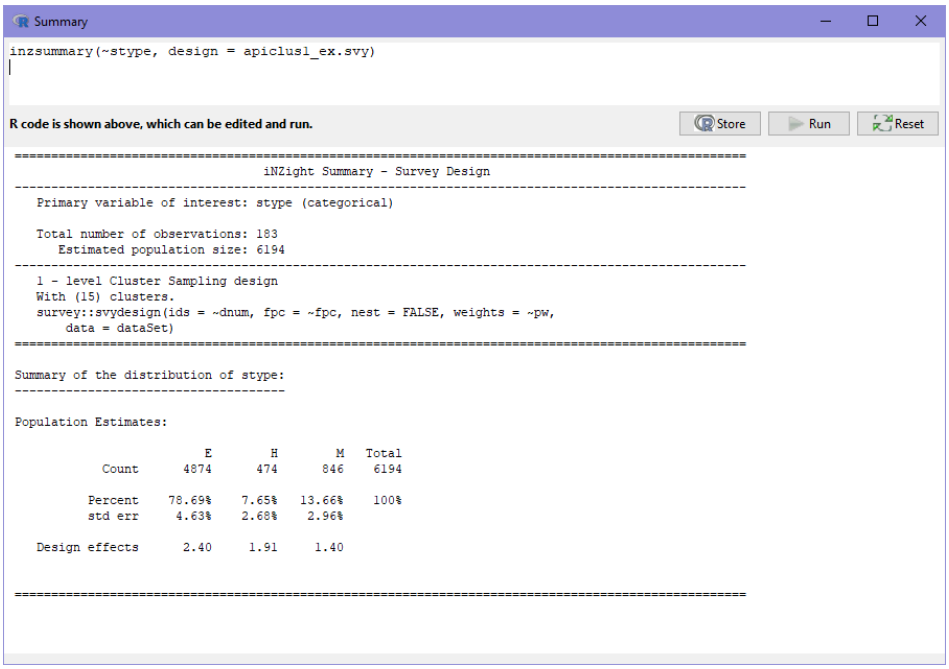

Figure 7: The SUMMARY window window provides simple summary statistics and, in the case of survey data, standard errors of these population estimates.

summaries of the population values, and are given along with the standard errors of the estimates, as shown in Figure 7.

Time series

Another data type many beginners will come across is *time series*, and is taught in the final year of high school statistics in New Zealand. The speciality of this data is that it must have one variable for observation times in a format that **iNZight** can understand, or can be specified manually if the user knows the time information. Then one or more variables can be displayed on the y axis versus time, typically connected by dots. Currently **iNZight** only supports time series with equally spaced and non-missing values.

iNZight provides capabilities for users to graph one or more time series on a graph, and overlays a smoother (controlled by a slider) on each one. Additionally, the series can be decomposed to show the trend, seasonal, and residual components (using seasonal-trend decomposition using LOESS (STL)). Animations are available to help with understanding how the various components combine to form the final series, and a Holt-Winters' forecast can be obtained by choosing the *forecast* plot type (Holt 2004; Winters 1960).

Figure 8 shows the time series module with quarterly visitor arrivals data for several countries loaded. The software automatically detects the `Time` column ("Date") when loaded, and draws the displayed graph without any user interaction. Users have a choice between *additive* and *multiplicative* models, and a slider to control the 'smoothness' of the LOESS smoother (in red). From the SELECT VARIABLE list, one or more variables may be chosen, while the graph type is selected from the list on the right.

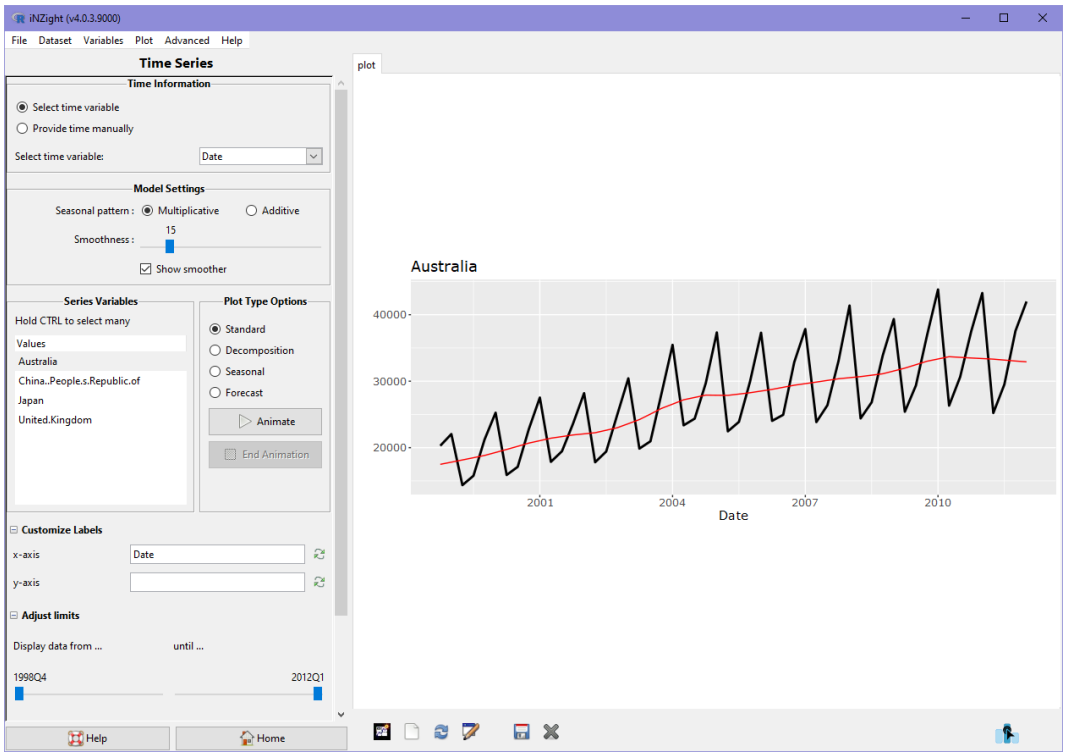

Figure 8: The time series module.

Maps

Geographical data is commonplace, and is often of interest to researchers but can be complex to create the appropriate graphics. **iNZight** includes a *Maps* module for exploring two types of geographical data: point-based data, in which observations are associated with latitude and longitudinal locations (for example earthquakes); and regional maps, which include data for specific regions which may be countries or areas within countries (regions, states, and so on). The functionality within the maps module call wrapper functions from the **iNZightMaps** package (Barnett and Elliott 2020).

For point-based observations, the simplest visualisation tool is to overlay the points on a map using functionality from, for which **iNZightMaps** uses the **ggmap** package (Kahle and Wickham 2013). The maps module in **iNZight** provides users with the ability to explore other variables in the dataset using size, colour, and transparency, as well as through faceting. A demonstration of this using New Zealand earthquake data is shown in Figure 9.

More complicated is region-type data, which require the added complexity of *shape files* which describe the boundaries of areas. An example of this is country data, which requires shape files for countries in the dataset describing the world map. **iNZight**'s maps module lets users choose the type of map they need for the data, and proceeds to match labels between the two datasets using several matching techniques since, for example, countries may be coded using full names or a code ("New Zealand" versus "NZ" versus "NZL"). Once done, users are free to pick variables to graph, and regions of the maps are coloured by this variable. Alternatively, if longitudinal data is available, *spark lines* can be drawn showing how the value of a variable changes over time.

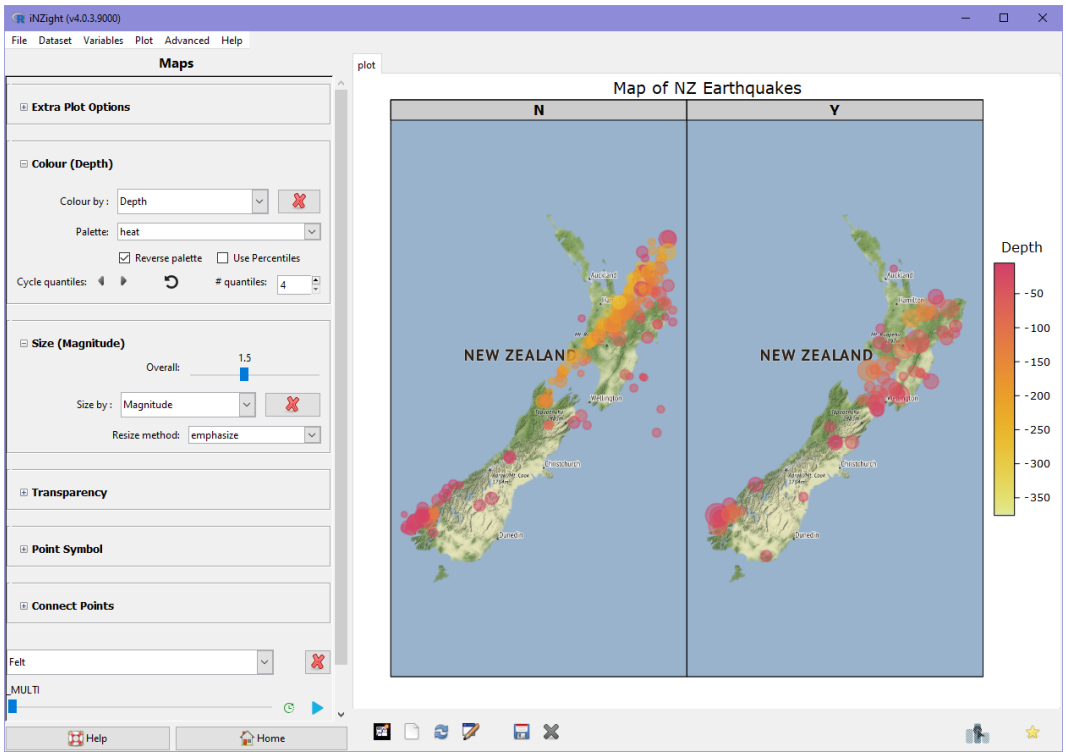

Figure 9: The maps module showing New Zealand earthquakes sized by magnitude, coloured by depth, and subset by whether or not they were felt.

Other data types and features

Besides these few examples, **iNZight** supports several other unique data types. Multiple response data arrises from "Choose all that apply" type survey questions, and need their own method of graphics to explore adequately. There is also a multivariate data add-on module allowing for principle components analysis and related graphs. Even more useful is the model fitting module, which allows users to fit complex linear and generalised linear regression models to data, including survey design data. In some cases, data may be frequency counts, which require some different handling also and can be specifed from the DATA menu.

Besides those examples listed above, **iNZight** has an add-on system Section 4 that allows developers to extend the interface to suit various type of data, or to perform specific types of analyses. The development means individual package developers, or researchs groups, can create custom modules that are shared either publically or privately with others.

2.6. Code writing for getting started with R

One feature prominent in the other R GUIs is the coding interface, which differs significantly from **iNZight**. R Commander provides a prominent "script" box that users can enter custom code into or is populated by menu-driven command boxes. Below the script box is an output terminal. Meanwhile **Deducer** is added onto the existing R Console, and similarly provides menu-driven commands to run code in the console. Each of these GUIs require some familiarity with R coding and an understanding of simple statistical terms and methods. **iNZight**,

however, is completely separate from the R console, providing an interface-only experience for beginners. All of the code used by various actions is stored and available for more advanced users to review their session and run it—with changes—in R manually.

The R script contains a history of all actions from importing the data through transformations and manipulations. The goal is to provide a record of what the user did, as well as something they can copy and paste into R and run themselves, editing where desired. This allows R learners to explore a dataset with a GUI tool and make the unique actions necessary, and then generate a script which they can build on and learn from.

Another feature is the inclusion of the R code box at the bottom of the interface, highlighted in FIGURE. This displays the code used to generate the current plot and, more importantly, can be edited by the user and run, somewhat similar to R Commander. When the user does so, the interface detects changes in the code and applies those changes to the GUI, providing a seamless way for users to begin experimenting with code whilst retaining the familiarity of the GUI. Users can also store the code for the current plot, which places it into the R script. A similar code box is displayed in the Get Summary and Get Inference windows, with plans to implement this behaviour throughtout **iNZight** in future.

The code used by **iNZight** uses a **tidyverse** (Wickham *et al.* 2019) workflow, as this provides an introduction to R with a simpler, verb-like syntax for data wrangling, and is used in the *R for Data Science* book (Wickham and Grolemund 2017). To demonstrate **iNZight**'s code-writing capabilities, Appendix A contains the script generated during the tour presented in this section.

3. Technical details

The interface for **iNZight** is developed entirely within R with the support of three main packages. **gWidgets2** (Verzani 2019) and **gWidgets2RGtk2** (Verzani 2020) provide a simple widget-based application programming interface (API) to building a cross-platform interface with R. The second package, **gWidgets2RGtk2**, is an interfacing package which provides a lower-level wrapper for the more complex functionality within the **RGtk2** package (Lawrence and Temple Lang 2010), which itself calls back to C libraries for the GTK+ windowing system (The GTK+ Team 2020). Together, these packages provide a platform- and library-independent API for creating windows with user inputs from R.

The framework used to build **iNZight** is an object oriented programming (OOP) framework, which is well suited to GUIs,[4] of which there are several within R. **iNZight** uses *reference classes*, as used by **gWidgets2**, to describe individual components of the interface. Each 'panel' is a *class*, with individual buttons, methods (actions), and even smaller sub-components which are themselves classes. OOP also allows for *inheritance*, allowing developers to describe a general class which can be shared to several related components, but which may have different layouts or methods. Figure 10 shows the **iNZight** GUI with some of the major class components annotated.

In addition to these "visible" class components, others exist behind-the-scenes. The prominent example is the '`iNZDocument`' class which stores the state of the application, including the data set, variable selection, any survey design information, and plot settings. The

[4] why

Figure 10: The reference class components of the **iNZight** interface, some of which are themselves made from several child objects.

'`iNZDataNameWidget`' component visible in the top-left of Figure 10 provides a list of documents the user can switch between and, from the DATA menu, merge several loaded datasets together.

The structure of each class is, in most cases, a set of attributes that the user can control, stored as *properties* of the class. There is also a set of *methods* which can be used by the class to react to user input, or perform actions. Most components have a main *action* method, which performs the primary action of the component. For example, the '`iNZFilterData`' class contains a `filter_data()` method which takes the user's input and passes it to one or more *wrapper* functions, such as `iNZightTools::filterNumeric()`. A skeleton example of the FILTER DATA window class is shown in Listing 1. In this oversimplified example, the user will be displayed a drop-down `gcombobox()` to choose a variable to filter on. When they click the FILTER button, the data will be filtered and passed back to the main GUI. Here, the method uses a `switch()` function to select the appropriate wrapper function within the **iNZightTools** package based on the user's chosen value of "type". The actual class for the FILTER DATA method is much more complicated, and includes reactive components so only the relevant inputs are displayed to the user.

Each major component has a similiar structure, and calls to various functions, many of which come from other **iNZight*** packages. For example, plots are generated by calls to `iNZightPlots::inzplot()`, while data import is handled by `iNZightTools::smart_read()`. This import function uses the file extension to guess the file type and load the data using the appropriate methods. The wrappers enfore separation of the interface and data logic so that the GUI is only concerned with the input values.

A second advantage of having components calling external functions is that these wrapper functions can be designed to include the lower-level R code used to generate the result, which the GUI can fetch from the returned data and attach to the script discussed in Section 2.6. Here is an example of the result returned by `iNZightTools::smart_read()`:

```
R> library("iNZightTools")
R> data <- smart_read("nls.dta")
R> cat(code(data), sep = "\n")

haven::read_dta("nls.dta")
```

The `iNZightTools::code()` function returns the R code attached to the resulting object, allowing a user to see that the **haven** package (Wickham and Miller 2020) was used to read this Stata file (`.dta`). Beginner R users need only learn the one function—`smart_read()`—but can easily dive into the underlying code and edit it as necessary to access advanced arguments.

While the GUI packages provide the structure of the visual GUI, it's the collection of R packages developed alongside **iNZight** that power the program. The main reason for creating separate packages was to force the separation of interface and data logic, but also to allow parallel development of a separate interface (Section 5.4) using the same wrapper functions. The collection of packages within the **iNZight** project are described in Table 2. Most of these packages have been designed with simple high-level interfaces that are both useful for connecting to the GUI, but also for beginners to use standalone.

3.1. Usage

```
iNZFilterData <- setRefClass(
    "iNZFilterData",
    propoerties = list(
        GUI = "ANY",
        data = "data.frame",
        type = "ANY",
        variable = "ANY",
        operator = "ANY",
        value = "ANY",
        ...
    ),
    methods = list(
        initialize = function(gui) {
            initFields(GUI = gui, data = gui$getActiveData())
            # ... construct GUI inputs ...
            # e.g.,
            type <<- gradio(c("Numeric value", "Factor levels", "Random"))
            variable <<- gcombobox(colnames(data))
            okbtn <- gbutton("Filter", handler = function(h, ...) filter_data())
        },
        filter_data = function() {
            filtered_data <- switch(svalue(type, index = TRUE),
                iNZightTools::filterNumeric(
                    data,
                    var = variable,
                    op = operator,
                    num = value),
                ...
            )
            GUI$update_data(filtered_data)
        }
    )
)
```

Listing 1: Reference class definition for filter window example.

Table 2: iNZight R package family

Package	Description
iNZight	The main package for the GUI
iNZightModules	An additional GUI package providing additional modules for the main **iNZight** program.
iNZightPlots	Provides plot function `inzplot()` along with `inzsummary()` for descriptive statistics and `inzinference()` for inference and hypothesis testing.
iNZightRegression	Plots and summaries of regression models, including from `lm()`, `glm()`, and `survey::svyglm()` objects.
iNZightTS	Time series visualisation, decomposition, and forecasting.
iNZightMR	Visualisation and estimation of multiple response data.
iNZightTools	A suite of helper functions for data process and variable manipulation.

At its core, **iNZight** is simply an R package that can be installed and run like any other, as covered in Section 5. Once installed, the main program can be started by creating a new instance of the main GUI class '`iNZGUI`', as demonstrated below.

```
R> library("iNZight")
R> ui <- iNZGUI$new()
R> ui$initializeGui()
```

For most users, however, the simpler wrapper function `iNZight()` can be called instead. This can optionally take a `data` argument, which will launch **iNZight** with the data loaded and ready to explore.

For development purposes, the former startup method is recommended, as it provides access to the '`iNZGUI`' object created to explore states and trigger actions for easier testing. In these two commands, the first returns the dimensions of current data, while the second sets the first variable drop-down value to `height`.

```
dim(ui$getActiveData())
```

```
[1] 500  10
```

```
ui$ctrlWidget$V1box$set_value("height")
```

4. The add-on system

Most users will likely find all they need within the main **iNZight** interface, able to explore and visualise their data quickly and easily. However, there are cases where, as mentioned earlier, specific types of analyses and graphics are required for special data types (time series and maps, as examples). Of course, the total range of data types available is close to limitless, and there are increasingly more R packages on CRAN every day providing new opportunities. Rather than requiring each new datatype or method to be manually coded into **iNZight** by the developers, we have crafted an *Add on* system allowing anyone to create their own **iNZight** modules.

Installing existing add-ons is easy. Users can either use the Module manager to add, update, and remove modules from our add-on repository, or from a custom URL or file. In all cases, the file is placed in the `modules` directory, which users (and developers) can also place files manually. All files in this directory are then displayed in the Advanced menu of **iNZight**, and when opened have access to the current data and other aspects of the interface.

The module files themselves describe a single class object which inherits from '`CustomModule`'. This parent class provides several methods, including the initialization of the module panel in the left-hand-side of the **iNZight** interface. Additional properties and methods can be written by the developers of individual modules. This opens up possibilities for teachers, research groups, or even R package developers themselves to write custom modules and distribute them to their desired audience.

As an example, Figure 11 shows a prototype of an upcoming Bayesian demographic modelling (Zhang *et al.* 2019) module which will be used by researchers and offical(?) organisations to

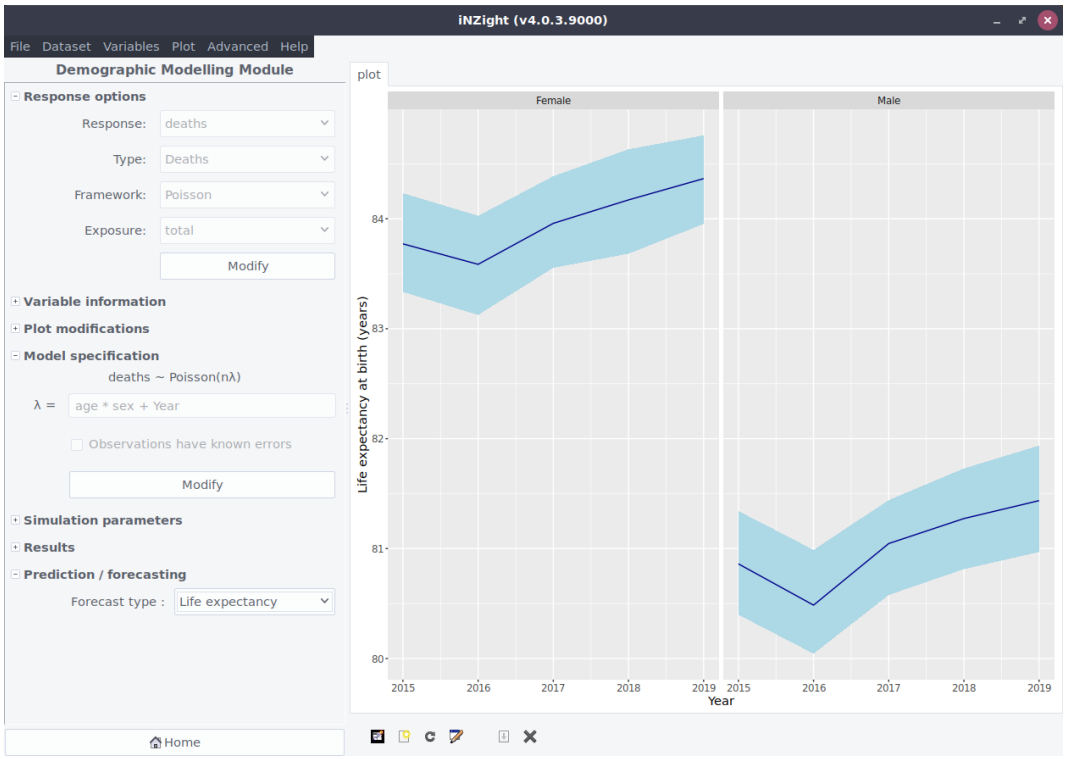

Figure 11: The prototype for a new Bayesian demographic modelling module for **iNZight**. In this example, life expectancy is estimated from death data.

do small-area demography. For example, estimation of life expectancy in small ethnic groups. This opens up advanced methods that were previously only available to proficient coders, who may now perform complex modelling procedures themselves. **This last para needs work**.

5. Installation and availability

As an R package, **iNZight** may be installed manually from the R console like any other package. We have an R repository available at `https://r.docker.stat.auckland.ac.nz` which hosts the most up-to-date versions of our packages. Most of these are now on CRAN, and work continues to publish the remainder. Since **iNZight** is a GUI, there are one or two additional system dependencies that need to be installed, with variations between operating systems, as discussed below.

5.1. Operating system specific requirements

The GTK windowing system is a cross-platform project with libraries available on Windows, macOS, and Linux. However, the install process varies between operating system in both steps and complexity. On Windows, the necessary files are available in binary form, and can be installed *after* installing **iNZight**: the **RGtk2** package will prompt the user to download and install these binaries on the first run.

On macOS, users are required to install XQuartz and the GTK+ framework before manually

compiling **RGtk2** themselves as, unfortunately, the binaries are no longer supported on CRAN. The complexity of this setup, and the lack of backwards compatibility of the macOS operating system, means we cannot officially support **iNZight** on macOS.

Finally, Linux comes in many flavours, each with different collections and names of libraries. However, the two dependencies are `xorg` and `gtk`, which are typically installed using the system package manager. For example, on Ubuntu 20.04, users can install the libraries thus:

```
$ apt-get install xorg-dev libgtk2.0-dev
```

Users of other operating systems should use the search functionality of their package manager to find the requisite libraries.

5.2. Windows installer

The primary audience for **iNZight** is students new to statistics, and are unlikely to have the computer literacy required by other GUIs to install and run the software (including R). To improve the accessibility of **iNZight**, we have built a custom installer that is effectively a self-extracting `.exe` file which includes a copy of R and the package library, so once installed **iNZight** is ready to go. This is by default installed into the user's `Documents\\iNZightVIT` directory.

In addition to the binaries and packages, the installer includes several shortcuts which can be double-clicked to launch R in a specific directory. This directory contains a `.Rprofile` file which automatically loads the **iNZight** package and launches the GUI. It also hides the R console, so users are presented with just the GUI which is more familiar to them. When started from the script, R is passed a command to terminate the R session once the user has finished using **iNZight**.

The **iNZight** installer also includes an Update script which, when launched, triggers an update to the R packages. This allows novice users to update to the latest version without needing to use R or re-download the entire installer. Additionally we include an Uninstaller which removes **iNZight** from the user's system if they so desire. It is not unusual for GUIs to perform package installation; R commander prompts the user to install several recommended packages on startup.

5.3. Docker image

Docker is a development and deployment solution for developers to build, test, and share their projects (Merkel 2014). It allows developers to construct build chains with all dependencies included within a single image file which can be downloaded by users to run the program without installing a large set of dependencies. We have built a docker image for **iNZight**, allowing users on macOS and Linux to run the software without installing the system dependencies. The downside of this approach is that the result is not as smooth as a native application, and also, as a GUI, requires a little more work from the user (particularly on macOS) to set up the necessary conditions for the app running in the container to project the GUI onto the host's screen. More information can be found at `https://github.com/iNZightVIT/docker-inzight`.

5.4. Online shiny version iNZight *Lite*

In recent years, many schools have adopted tablets or Chromebooks instead of Windows laptops, neither of which are capable of running R and, therefore, **iNZight**. To provide these students with equal opportunity, we created an online version of **iNZight** that uses **shiny** (Chang *et al.* 2021) as the GUI framework instead of GTK, named **iNZight** *Lite*.

Since most of the data-logic occurs in separate packages, porting **iNZight** to the web was simply a case of coding the interface elements and passing user inputs to the wrapper functions. This also means that the underlying code is the same between programs, so the *output* is the same in both cases, making it easier for teachers and researchers to use one or the other. We attempted to keep the interfaces as similar as possible, but there are obvious differences in the capabilities of the GUI toolkits.

The online version runs inside its own docker container on a remote Amazon Web Services server. Interested users could run the container locally by installing docker. Most users, however, will simply access the web interface by heading to `https://lite.docker.stat.auckland.ac.nz` in a browser, including on a tablet. There are also a set of URL parameters which can be passed to the **iNZight** *Lite* instance, including a URL for a dataset to automatically load.

Within the container, shiny is used to create the visual controls and perform reactivity events. A users data is stored on the server temporarily, and is only accessible from that user's session: it cannot be shared or accessed by other users. However, we still would not recommend users upload confidential or otherwise sensitive data; this would be better explored using either the desktop version or by running **iNZight** *Lite* locally.

6. Summary and future work

Newcomers to statistics often need to learn both how to code using R whilst simultaneously learning the basic skills for data exploration. By providing an easy-to-use GUI, **iNZight** allows beginners to focus on the fun part of exploring and analysing data, developing these essential skills before embarking on the more challenging part of learning to code. The software is *variable first*, meaning users do not need to first know complicated statistical terminology to get the most from their data: the software provides a list of applicable methods given their current variable choice.

Similarly, data manipulation techniques such as filtering, renaming levels of factors, and even specifying survey designs, is all presented in simple, step-by-step windows, many of which provide previews that help users to tweak the inputs to get the desired output. As mentioned above, many users will eventually need to learn to code with R, so **iNZight** includes some simple tools for helping that migration: code writing to a session script, and a reactive code panel for modifying and running code for the current plot.

Statistics and data science is an ever expanding field, with new R packages added to CRAN daily. **iNZight** includes an add-on system which allows other developers outside of the development team to create and share modules which **iNZight** users can install and use on top of **iNZight**'s existing feature set. Since **iNZight** is available as a standalone program on Windows, package developers have an opportunity to reach audiences they might not previously have been able to.

6.1. Future Work

A lot of new features and functionality are planned for the future of **iNZight**, the foremost being the ability to interact with more complex datasets, particularly those saved within a database, with as much processing done within the database as possible to speed up the interface for possibly large datasets. This, along with other advances, will make **iNZight** a useful tool for not only learners but researchers and organisations alike, including capabilities for the software to connect to secure databases behind a firewall and allowing researchers without coding skills access to it.

The main issue with **iNZight** at present is its reliance on GTK, which has been discontinued on macOS. Exploration into possible alternative frameworks is ongoing, with desire to develop a fully cross-platform application so users from all backgrounds can make use of the software.

Acknowledgments

iNZight is a free to use, open source software. The work would not have been possible without the support of: The University of Auckland; Census at School; Ministry of Business, Innovation, and Employment; Te Rourou Tāātaritanga; Statistics New Zealand; and the Australian Bureau of Statistics. We also thank the technical support of the University of Auckland IT services for providing hosting services for our repository and Lite servers.
